

AN INTRODUCTION

Project *State*.

A local-first intelligence layer for modern knowledge work.

i. The problem

Modern work is *fragmented*.

A single project lives across email, chat, drives, repos, and people's heads. Context disappears. Decisions get buried. Reporting becomes manual.

ii. The solution

A living *project state*.

Project State organizes that activity into a durable memory layer — goals, milestones, decisions, risks, communications — stored as plain files, owned by the project itself.

iii. The result

Context that *compounds*.

Teams and AI alike can see what happened, what matters now, and what should happen next — without anyone having to remember it.

01
SIGNAL

`work-state ~/.work-state/`
Harvests activity from GitHub, Gmail, Slack, and Google Drive into a structured personal activity log.

ANSWERS
what has been touched, and by whom?

02
EXECUTION

`project-state ./project-state/`
Per-project depth: milestones, phase gates, decisions, risks, document curation, IP, funder reporting.

ANSWERS
how is this project actually going?

IN SHORT

A portable organizational memory system that captures the evolving state of a project, team, or business initiative — stored inside the project itself, in durable local files, as a persistent source of truth that large language models can query, summarize, and use to support execution.
